Rank, Model #, Decision and Ensemble

What each number on the Screener means, with today's data (closes to 2026-10-28).

In one line. Rank comes from the *screen*: how good the company looks and what analysts think. **Model #**, **Decision** and **Ensemble** come from the *forecasting models*: where the price is expected to go over the next 20 sessions. Model # and Decision are the same ranking written two ways; Decision is the Ensemble wherever the ensemble could score the stock.

1. Two systems

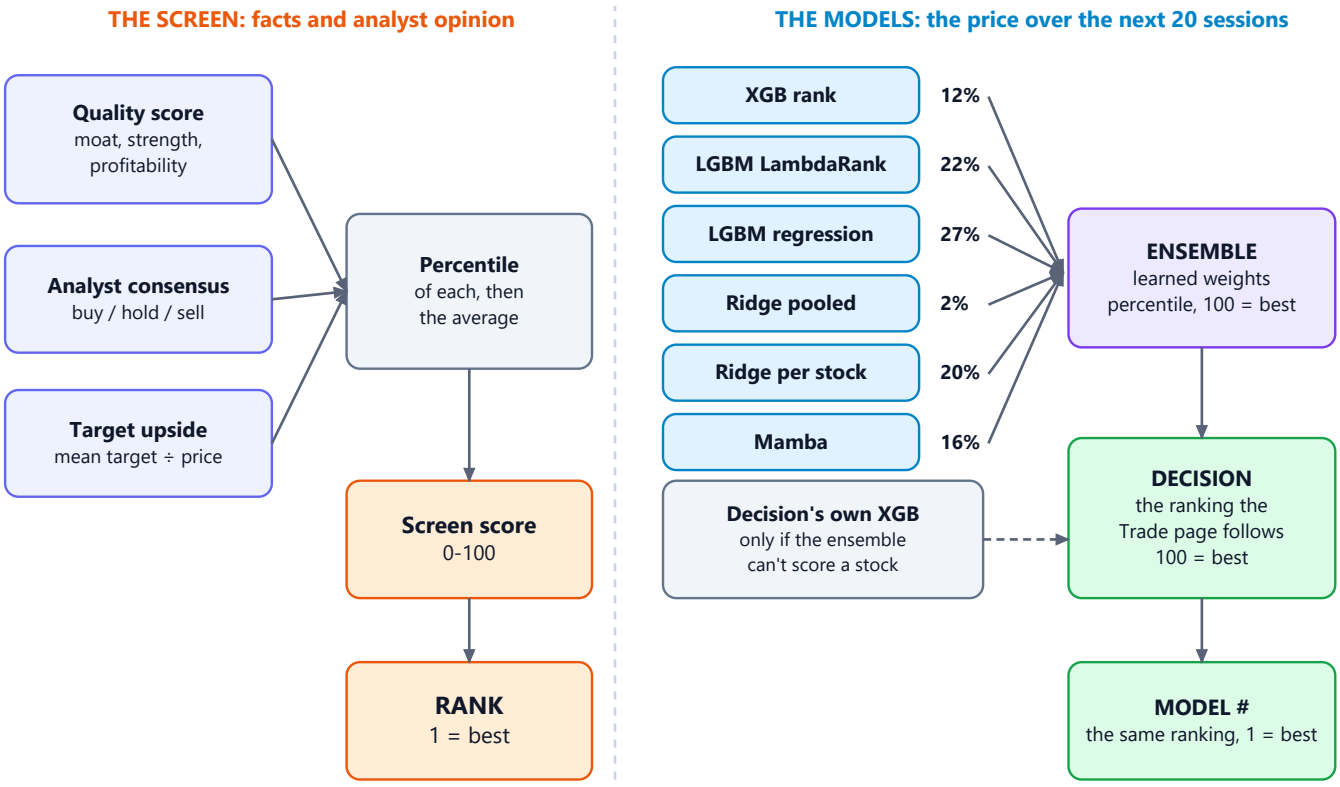

Figure 1. Left, the screen: three inputs → one score → Rank. Right, the models: six models combined with learned weights → Ensemble → Decision → Model #. The dashed arrow is the fallback.

2. Where each column appears

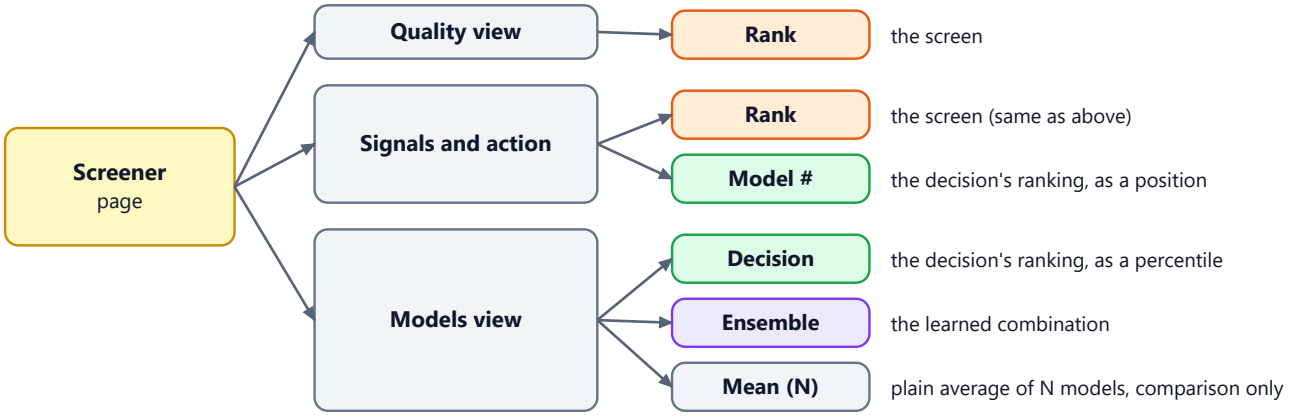

Figure 2. The Screener's three views and the columns they show. Orange: the screen. Green: the models' deciding ranking. Purple: the ensemble.

3. Percentile and position: one ranking, two scales

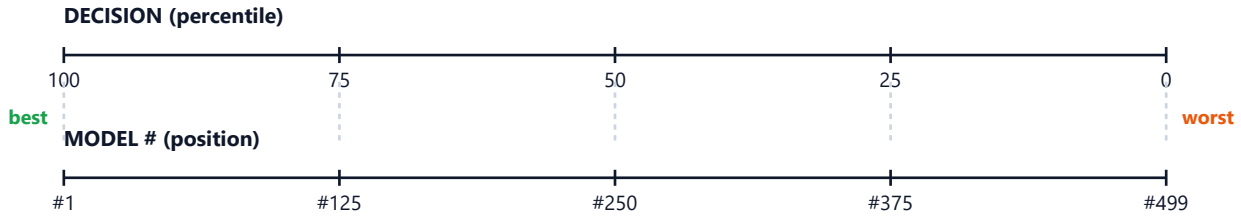

Figure 3. Decision gives a percentile (100 = best); Model # gives the place (1 = best). A stock at the 99th percentile is about #5 of 499.

4. The two systems often disagree

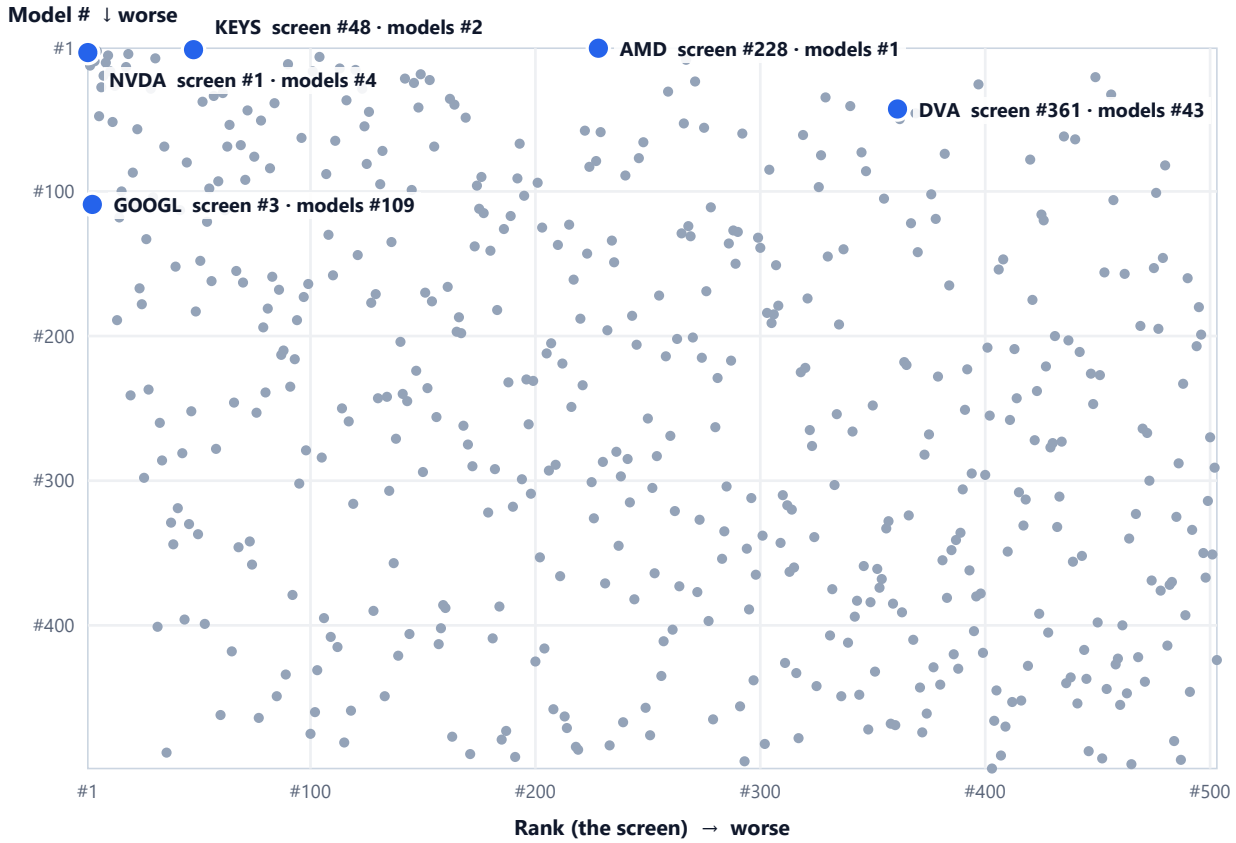

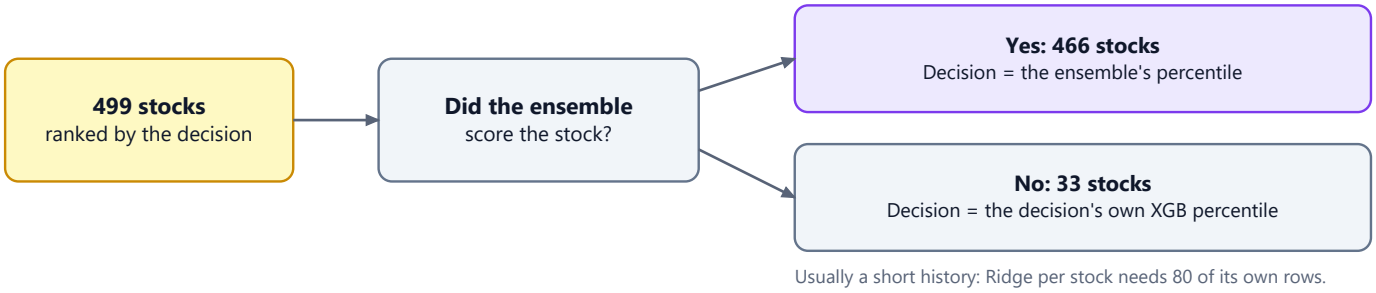

Figure 4. Every stock with both numbers today (495). Top left: both like it; bottom right: neither does. Their rank correlation is 0.33: related, far from the same.

A good company is not the same as a stock the models expect to rise in the next month. GOOGL screens near the top but sits in the middle for the models; AMD is the models' first pick with an average screen rank. The two answer different questions, so read them side by side.

5. When Decision and Ensemble differ

Usually a short history: Ridge per stock needs 80 of its own rows.

Figure 5. The ensemble needs all six of its models; where one is missing, the decision uses its own XGBoost ranking for that stock.

Because those stocks are ranked together with the ensemble's, a stock's Decision percentile can differ slightly from its Ensemble percentile even when the ensemble scored it (DVA today: 91.9 against 92.1).

6. Summary

Column	Comes from	Answers	Scale	Where
Rank	the screen: quality, analyst consensus, target upside	Is this a good company that analysts like?	1 = best	Quality view; Signals and action
Ensemble	six models with learned weights	Which stocks should do best over 20 sessions?	100 = best	Models view
Decision	the ensemble, else the decision's own XGB	What the Trade page follows	100 = best	Models view
Model #	the Decision ranking	The same, as a place	1 = best	Signals and action
Mean (N)	plain average of N models	Comparison only; decides nothing	100 = best	Models view

None of these rankings is validated for trading. The screen is untested for returns, and the models' tested skill is small; the learned ensemble did not beat a plain average in testing. See *AlphaDesk_Model_Design.pdf* for how each model is built and tested.
